Desmoglein<sub>3</sub>

ECM

# Functions of ECM

## Functions as adhesive substrate

- tracks to direct migratory cells
- concentration gradients for haptotactic migration

## Provides structure

- defines tissue boundaries
- provides integrity and elasticity to developing organs
- degraded by invasive cells during development and disease

## Presents growth factors to their receptors

- controls spatial distribution of ECM-bound surface molecules
- facilitates crosstalk between growth factor receptors and ECM receptors

## Sequesters and stores growth factors

- allows for spatio-temporal regulation of factor release
- organizes morphogen gradients
- mediates release of factors in the presence of appropriate cell-mediated forces or proteolytic degradation

## Senses and transduces mechanical signals

- defines mechanical properties permissive/instructive to cell differentiation
- activates intracellular signaling through interaction with cell-surface receptors
- engages cytoskeletal machinery and synergizes with growth factor signaling

## Extracellular matrix (ECM)

a) kollagének

b) proteoglikánok, hyaluronsav

c) elasztin

d) glikoproteinek, pl.: fibronectin, laminin, tenascin

Cells secure their survival and regulate growth and differentiation through adhesive interaction with surrounding extracellular matrix

Fibronectin

# Fibronectin

Fibronectin Structure

Figure 6.32.

Fibronectin in the developing frog embryo. (A) Fluorescent antibodies to fibronectin show fibronectin deposition as a green band in the *Xenopus* embryo during gastrulation. The fibronectin will orient the mesoderm movements of the cells. (B) Structure and binding domains of fibronectin. The rectangles represent protease-resistant domains. The fibroblast-binding domain consists of two units, the RGD site and the high-affinity site, both of which are essential for cell binding. Avian neural crest cells have another site that is necessary for them to migrate on a fibronectin substrate. Other regions of fibronectin enable it to bind to collagen, heparin, and other molecules of the extracellular matrix.

Lamina basalis, membrana basalis

# membrana basalis / lamina basalis

### Epithelial cell

Basal domain

**1** The **basement membrane**, an extracellular component in direct contact with the basal domain of epithelial cells, is visible under the light microscope after staining with the **periodic acid–Schiff (PAS) reagent technique**.

**2** At the **electron microscopic level**, the basement membrane is defined by two layers or laminae:

1. A **basal lamina**, which contains laminin, fibronectin, type IV collagen, heparan sulfate proteoglycans, and nidogen (also called entactin).

2. A **reticular lamina**, which contains type III collagen (also called reticular fibers)

The components of these two laminae are glycoproteins. They are **PAS positive**.

Basal lamina

Reticular lamina

Under **light microscopy**, both laminae are resolved as a single **basement membrane** after staining with the **PAS technique**.

Each lamina can be resolved as a separate entity by **electron microscopy**.

# Integrinek

Figure 6.37.

Two types of activation by cell adhesion molecules. (A) Cell-substrate adhesion molecules such as integrins may transmit a signal from the cytoplasmic portion of the integrin protein to the Ras G protein through a cascade involving caveolin and Fyn proteins. (B) The FGF receptors may be “hijacked” by cell adhesion molecules and dimerized. They may be brought together by the interaction of opposite cell adhesion molecules, or the “crosslinking” of FGF receptors by the apposing cell membrane may activate their kinase domains.

**Figure 1.** PCR amplification of  $\beta$  actin, integrins  $\beta 1$ ,  $\beta 3$ ,  $\beta 5$ ,  $\alpha 2$ ,  $\alpha 3$ ,  $\alpha 6$  and  $\alpha 7$ , ZO-1, L selectin (L sel), P selectin (P sel), DSC-2 and E-cadherin (E-cad) from cDNAs amplified from three individual embryos (1,2,3) at each of the pronucleate (PN), 2-cell (2C), 4-cell (4C), 8-cell (8C) and blastocyst stages of development.

## integrins in the preimplantation embryos

Expression of cell adhesion molecules during human preimplantation embryo development.

Bloor DJ<sup>1</sup>, Metcalfe AD, Rutherford A, Brison DR, Kimber SJ.

Mol Hum Reprod. 2002 Mar;8(3):237-45.

**Figure 2.** Confocal images of fixed human blastocysts showing protein localization of  $\beta 1$  (expanded blastocyst, d6 and cavitating embryo, d5) and  $\beta 5$  integrin subunits (indicating position of inner cell mass and arrowheads showing cell surface localization of  $\beta 5$  on polar trophoctoderm),  $\alpha 6$  integrin (arrowhead indicates staining on the trophoctoderm at site of hatching from the zona pellucida), E-cadherin (E-cad) and ZO-1 (arrowheads indicate localisation of signal at cell junctions). Negative control images of blastocysts incubated with rat IgG (rIgG), mouse IgG (mIgG) or rabbit pre-immune serum (RPI). Scale bars = 25  $\mu$ m.

# Sejt-migráció

Figure 1: Integrin-mediated cell adhesion to the ECM. (a) Suspended cells adhere to the surface of ECM via integrins. Some of the nascent adhesion contacts grow and form mature focal adhesions (FAs). (b) Integrins function as a heterodimer composed of  $\alpha$ - and  $\beta$ -chains. (c) The cytoplasmic portions of integrins recruit multiple cellular proteins and form cross-linked platforms to regulate both the actin cytoskeleton and signal transduction.

### Focal adhesion migrating cell

Adhesion is closely coupled with the protrusions of the leading edge of the cell (filopodia and lamellipodia). Adhesions (nascent adhesions) initially form in the lamellipodium (although adhesions may also be associated with filopodia) and the rate of nascent adhesion assembly correlates with the rate of protrusion. Nascent adhesions either disassemble or elongate at the convergence of the lamellipodium and lamellum (the transition zone). Adhesion maturation to focal complexes and focal adhesions is accompanied by the bundling and cross-bridging of actin filaments, and actomyosin-induced contractility stabilizes adhesion formation and increases adhesion size.

# Morphological Processes of Tube Formation

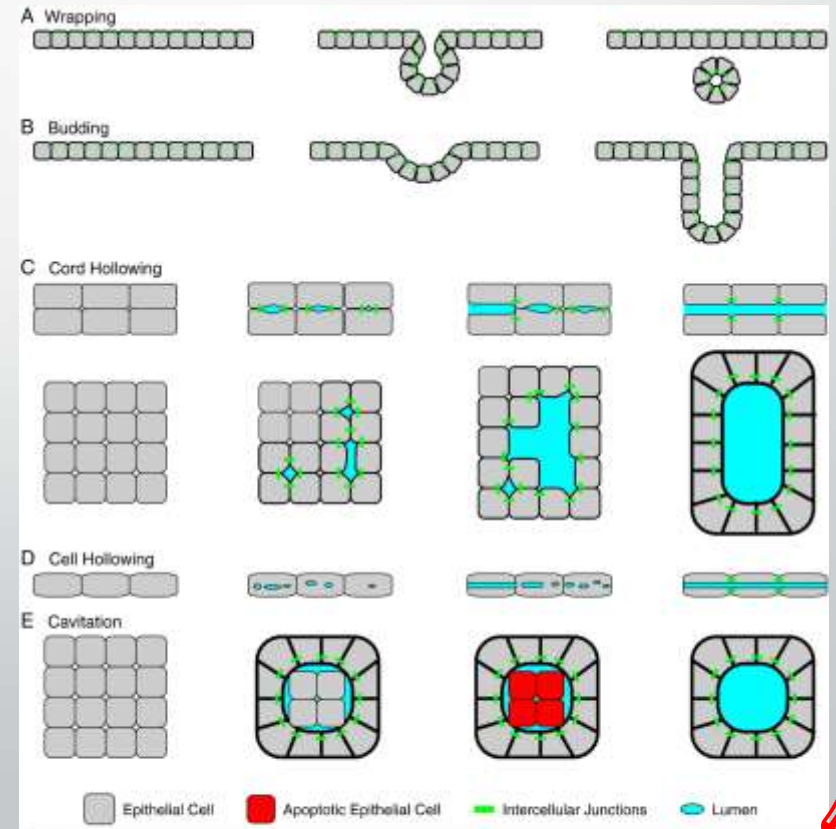

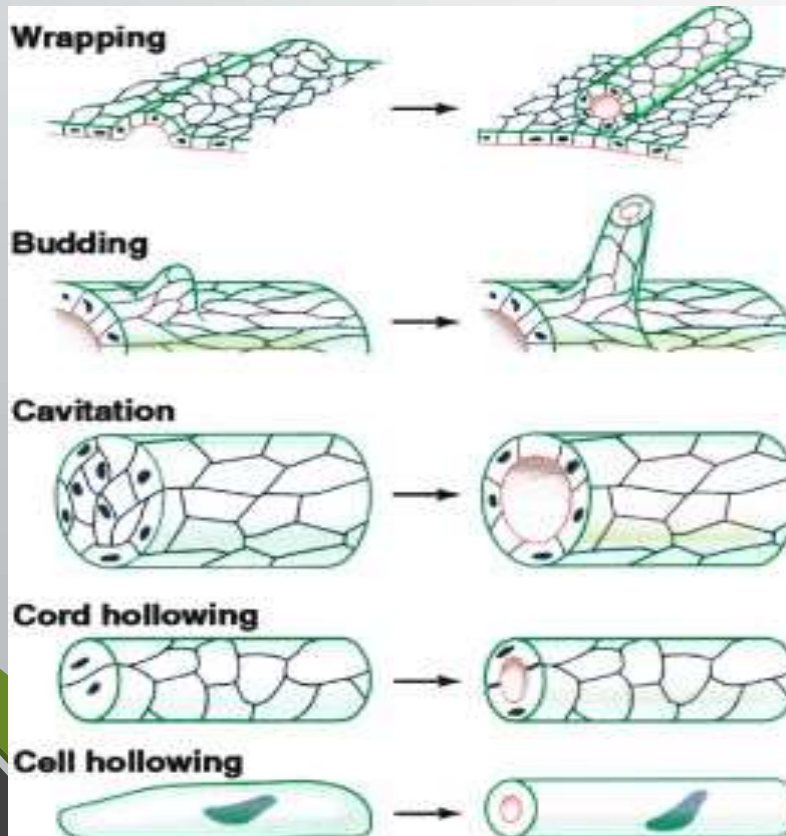

**Wrapping:** a portion of an epithelial sheet invaginates and curls until the edges of the invaginating region meet and seal, forming a tube that runs parallel to the plane of the sheet.

**Budding:** a group of cells in an existing epithelial tube (or sheet) migrates out and forms a new tube as the bud extends. The new tube is a direct extension of the original tube.

**Cavitation:** the central cells of a solid cylindrical mass of cells are eliminated to convert it into a tube.

**Cord hollowing:** a lumen is created de novo between cells in a thin cylindrical cord.

**Cell hollowing:** a lumen forms within the cytoplasm of a single cell, spanning the length of the cell.

# Tubulus képződés

## Types of Simple Epithelial Tubes

Tube walls are formed by polarized epithelial cells with their apical membrane surface (red) facing inward toward the lumen space, and their basal surface (green) exposed to the extracellular matrix.

(A) A multicellular tube with four curved cells in the cross-section of the tube.

(B) A unicellular tube formed by a single cell, rolled up to enclose the lumen, and sealed with an autocellular junction.

(C) A unicellular tube with the lumen in the cytoplasm of the cell. There is no autocellular junction; the tube is "seamless."

(D) Branching in the mammary gland of a mouse in early pregnancy.

### Branching Morphogenesis at the Cellular Level

Schematic representation of a typical branching process. In many cases, a subgroup of cells (schematically illustrated in black in [B]) of a preexisting epithelium (A) is assigned to undergo branching morphogenesis by the expression of a specific subset of transcription factors and/or signaling mediators. As a consequence of this determination step, these cells invaginate or form a primary bud (C). Branch formation is then initiated in the invaginated (or budded) structure (from [D] to [E]) and the branching process can be reiterated numerous times (F). In addition, lateral branches can be induced. After the branching process, complex processes lead to the development of specialized terminal structures, a process that is different in different branched organs. Because the development of the vascular system does not in general follow the scheme outlined in this figure, we have excluded in this review a description of how the branched aspects of the arterial and venous network arises.

### Branching Morphogenesis at the Subcellular Level

Control of branch formation at the subcellular level in the *Drosophila* tracheal system. The FGF receptor tyrosine kinase *Breathless* is expressed in all tracheal cells. The activation of the receptor in the cells at the tip of the outgrowing branches, presumably due to their proximity to the localized source of the FGF ligand *Branchless* (blue), leads to the formation of filopodial cell extensions (A). Cells at the tip of the bud subsequently form broader cell extensions (B), and ultimately move toward the *Bnl* source (C and D). In (E) is shown a confocal image of a tracheal branch of a stage 14 *Drosophila* embryo expressing a membrane-bound version of GFP specifically in tracheal cells. One can clearly see that only the two leading cells produce filopodia (see also Sutherland et al. 1996 and Ribeiro et al. 2002).

# Development of mammalian's lung

Fig. 3

The underlying principle is again a mesenchymal-epithelial cell-cell interaction mediated by FGF. Epithelial cells, expressing *FGF receptor*, respond to the secretion of FGF from nearby mesenchyme by bud formation and bud extension towards the FGF source. Exposure of the branch tip to high concentrations of FGF induces the expression of secondary genes in the tip such as bone morphogenetic protein 4 (*BMP4*), sonic hedgehog (*Shh*) and a mammalian sprouty ortholog (*Sprouty 2*), thus, turning the tips of the bronchial branches into signaling centers. *BMP4* inhibits epithelial cell proliferation limiting branch extension. *Shh* is proposed to inhibit *FGF10* expression in the mesenchyme near the tip, which splits *FGF10* expression promoting the next round of branching and *Sprouty2* (like drosophila *sprouty*) restricts branching to the tip of the branch.

Figure 15-26 Molecular aspects of outgrowth and branching of the respiratory tree. A, The tip of an elongating respiratory duct. FGF-10 secretion in the mesenchyme stimulates the growth of the tip of the epithelial duct toward it. B, The prelude to branching. Inhibition of FGF-10 signaling at the tip of the duct leads to stabilization of that area. C, Cleft formation.
