SEMMELWEIS  
EGYETEM 1769

# Tooth development

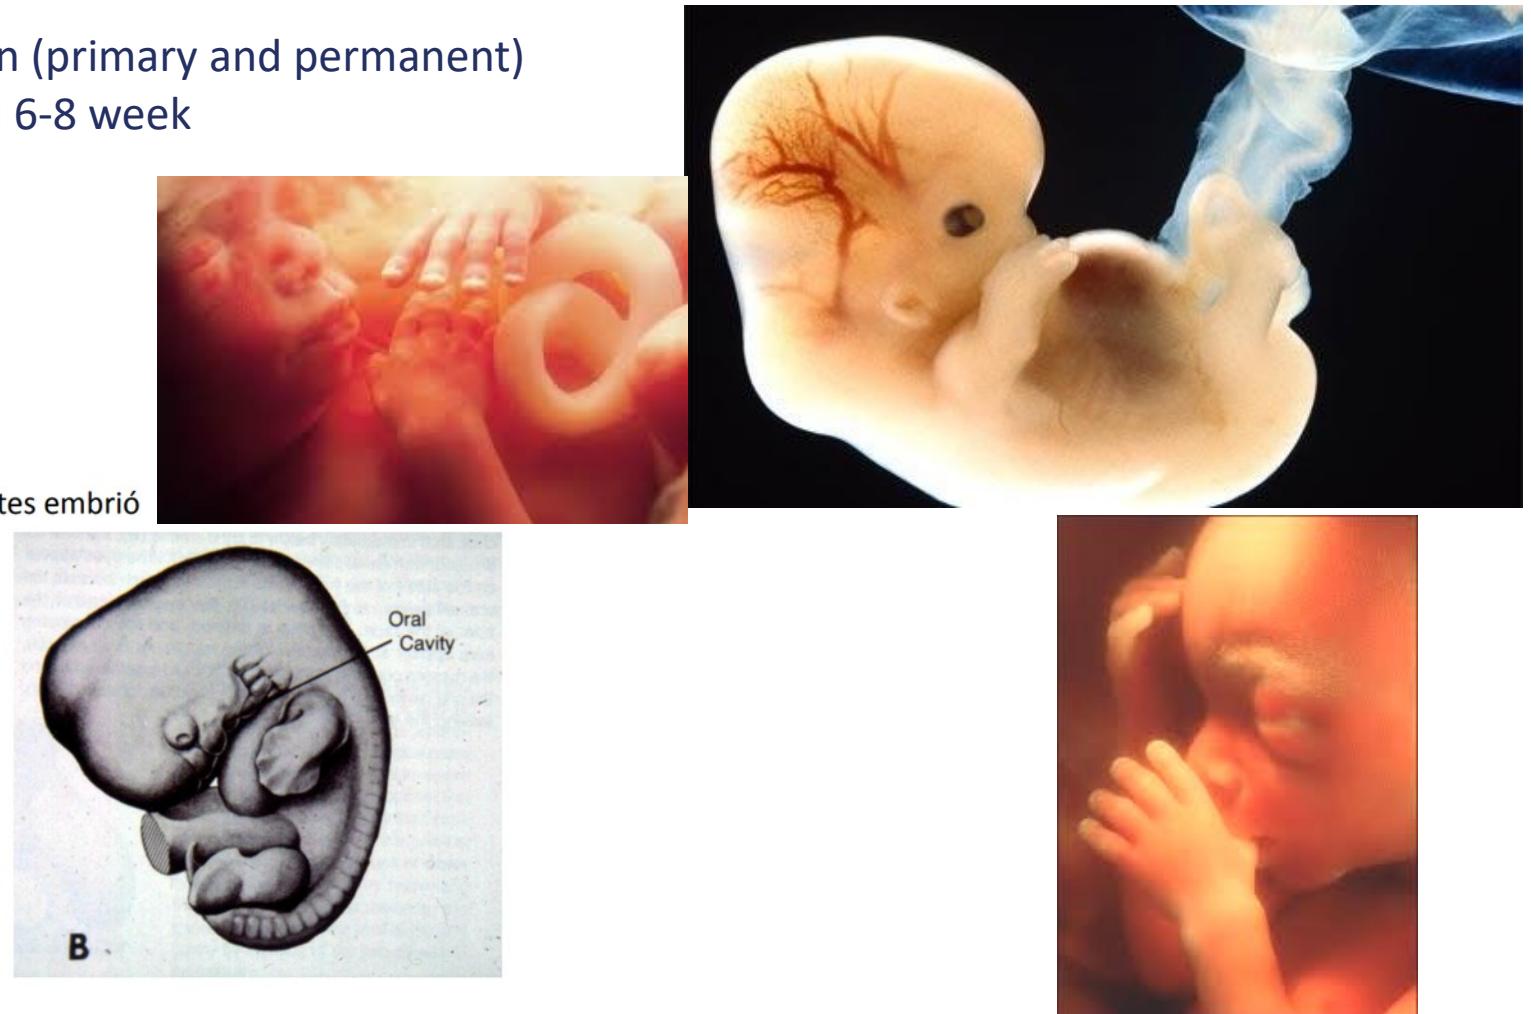

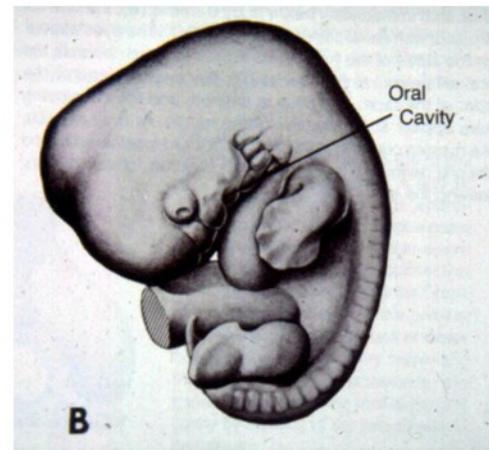

Human- Diphyodont: two types of dentition (primary and permanent)

Tooth development starts in the embrional 6-8 week

## Embryo and Fetal Growth

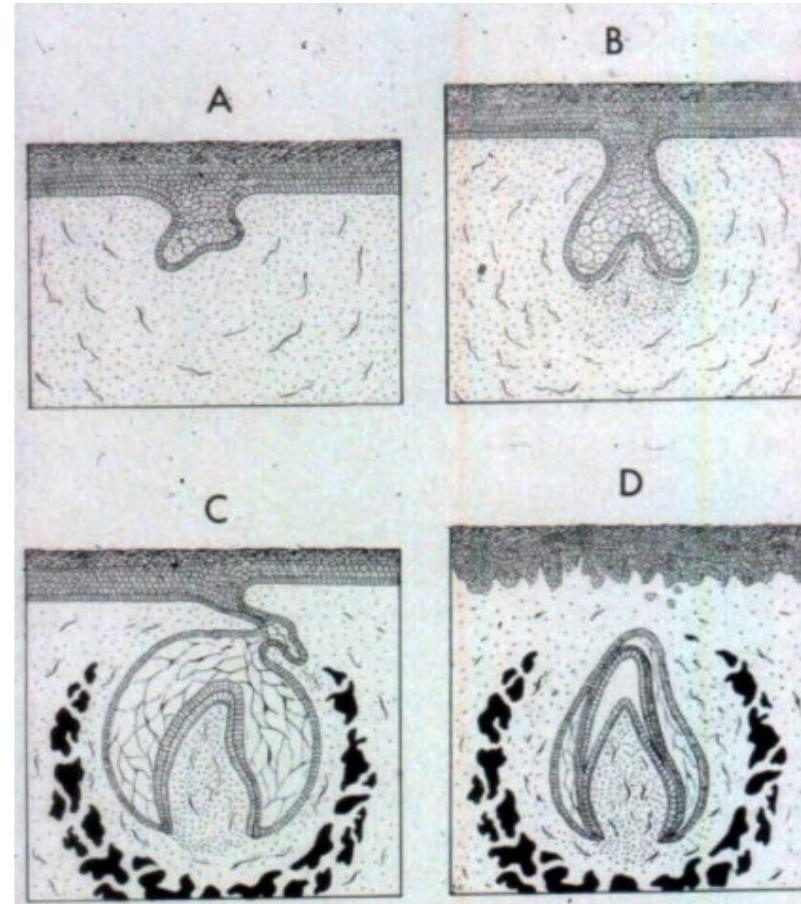

7 hetes embrió

# Tooth development

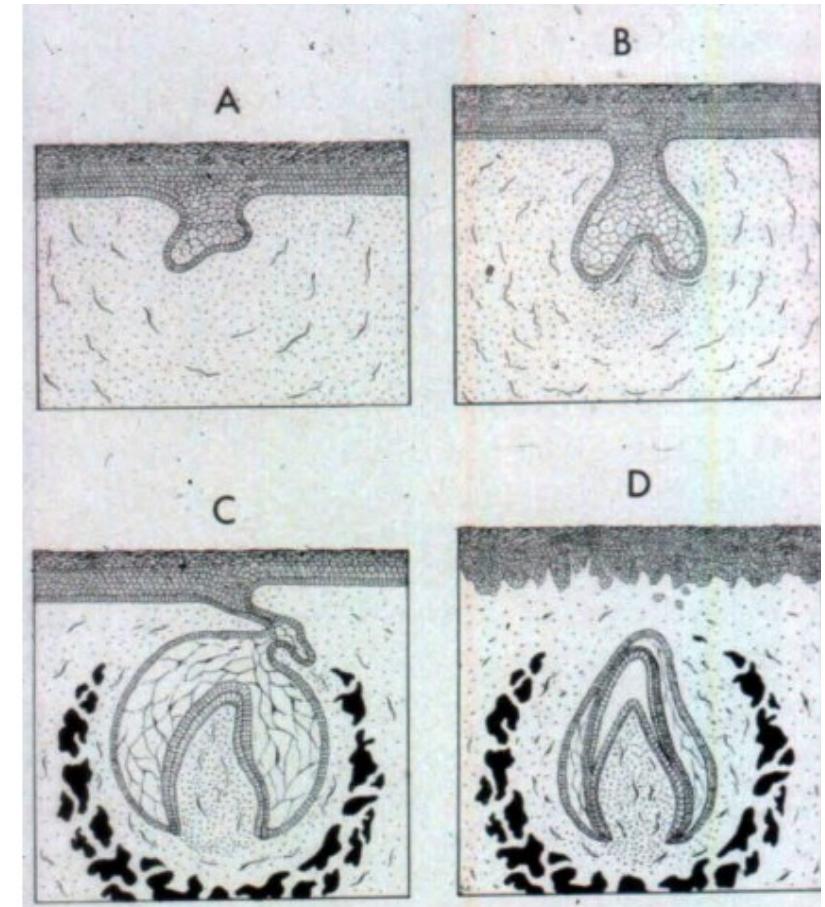

- 1. Dental lamina
- 2. Bud stage
- 3. Cap stage
- 4. Bell stage
- 5. Dental germ

Rózsa N., Gábris K., Tarján I.: Gyermek és Ifjúsági Fogászat, Semmelweis Kiadó, 2023 Budapest

# Tooth development

- **Inductio** (6-7th week i.u.)
  - Initiation stage
  - dental lamina
- **Proliferatio**
  - Tooth bud (8th week i.u.)
  - Cap stage (9-10th week i.u.)
- **Histodifferentiatio**
  - Bell stage (11-12th week i.u.)
  - Toothgerm
- **Calcificatio**
  - Enamel
  - Dentin
- **Eruptio**
  - Root (Hertwig's epithelial seath)

Rozsa N., Gábris K., Tarján I.: Gyermek és Ifjúsági Fogászat, Semmelweis Kiadó, 2023 Budapest

# Tooth development

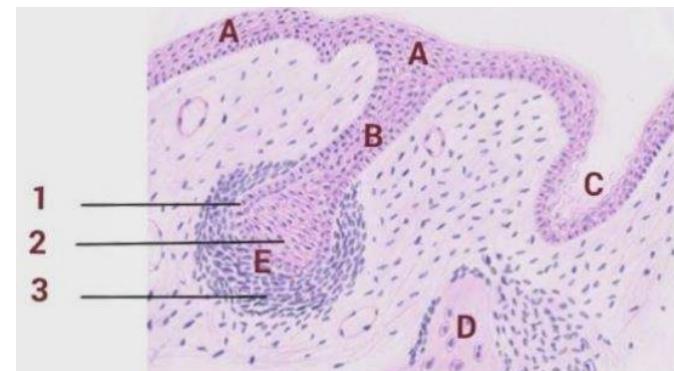

## 1. Induction ( 6-7 week)

- Medial nasal process + maxillary process--> superior processus alveolaris
- Mandibular process 2 side--> lower alveolar process
- 10-10 primary teeth germs appear in both jaw

In the elementary oral cavity (stomodeum) a horseshoe-shaped epithelial thickening appears on the upper and lower edge, pushes deep, splits in a Y shape

- Outer part: lip bar
- Inner part: dental lamina (lamina dentalis) (can be an eruptive cyst)

A- stomodeum epithelium  
B- lamina dentalis  
E- Tooth bud

Rózsa N., Gábris K., Tarján I.: Gyermek és Ifjúsági Fogászat, Semmelweis Kiadó, 2023 Budapest

# Tooth development

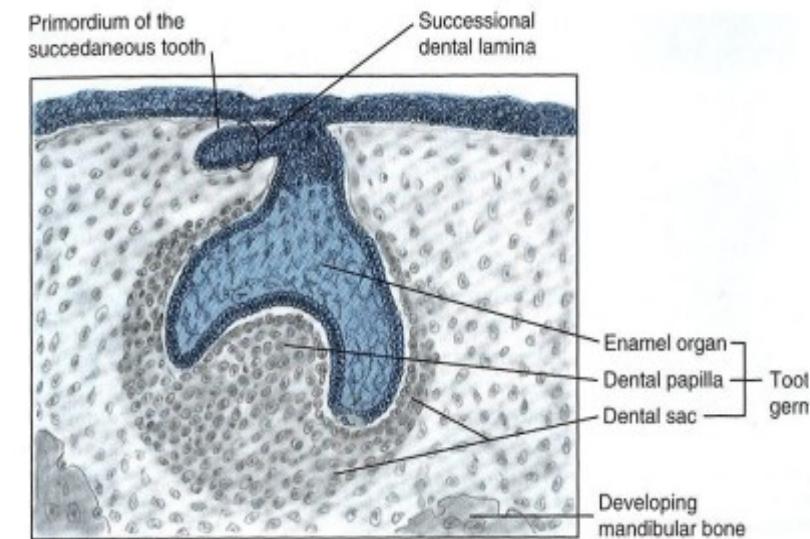

## 2. Proliferation:

- Bud stage (8th week)

- On the outer side of the dental lamina, epithelial globules appear - enamel buds (10-10)

- A compaction of ectomesenchyma around it = dental papilla  
Dental papilla + enamel bud = tooth germ

- Enamel organ is connected to the surface's multilayered non-keratinized squamous epithelium by the dental lamina

Rózsa N., Gábris K., Tarján I.: Gyermek és Ifjúsági Fogászat, Semmelweis Kiadó, 2023 Budapest

# Tooth development

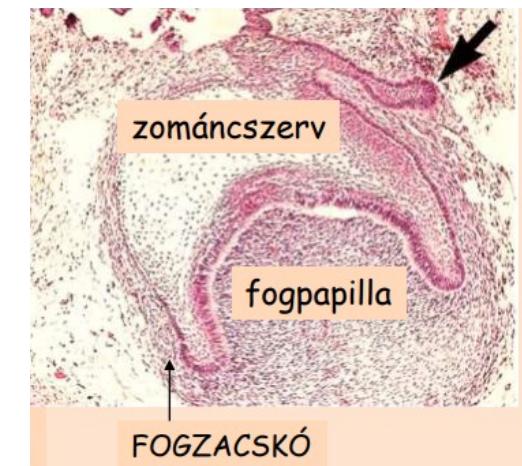

## 3. Histodifferentiation:

- Cap stage (weeks 9-10):
- On the aboral side of enamel bud a mesenchymal compaction presents - dental papilla
- Dental papilla pushes in the cells.

Differentiation:

*Enamel organ*

- outer enamel - outer cell cubical shape
- enamel pulp (str. reticulare) - star-shaped
- str. Intermedium enzymes (enzymes)
- internal enamel epithelium - cylindrical cells,  
preameloblast-ameloblast

Rózsa N., Gábris K., Tarján I.: Gyermek és Ifjúsági Fogászat, Semmelweis Kiadó, 2023 Budapest  
Gallatz K: Fogak fejlődése – Tantermi előadás

# Tooth development

## 3. Histodifferentiation:

-Bell stage (10-12 weeks)

-Induction: to the mesenchyme to epithelium

-Tooth bud grows, change the shape to bell shape and the *formation of dental crown hard tissues begin.*

Enamel organ:

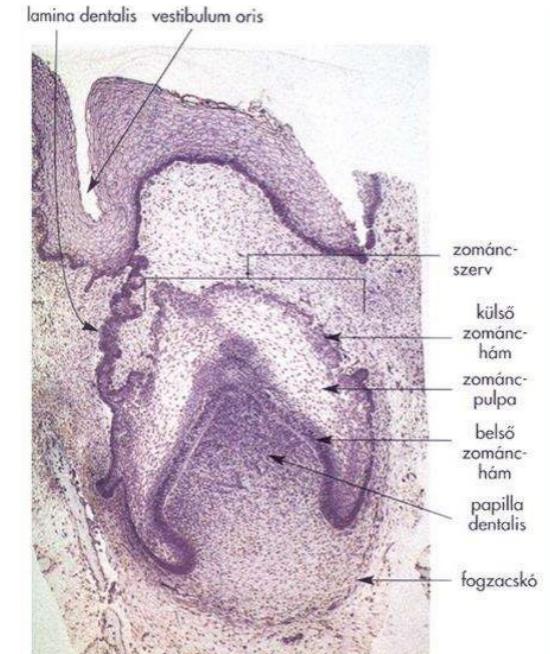

external enamel

str. Reticular (GAG)

str. Intermedium (enzymes)

inner enamel epithelial cells- preameloblast-ameloblast

their nutrition come from the dental papilla

Rózsa N., Gábris K., Tarján I.: Gyermek és Ifjúsági Fogászat, Semmelweis Kiadó, 2023 Budapest  
Gallatz K: Fogak fejlődése – Tantermi előadás

# Tooth development

## 5. Calcificatio (10-20 weeks, then 3-4 years of life)

- Enamel is produced from the tip of the tooth towards the cervical region
- Enamel thickness increases - ameloblasts are pushed towards the enamel pulp
- When they contact with the outer enamel layer - completion of enamel formation

### *Maturing phase:*

- Mineralization is taking place!
- 97% mineral material, 2-3% organic material
- Final product Nasmyth membrane / cuticle dentis
- End of enamel production: ameloblasts die

Fehér E: Fogfejlődés, fogáttörés in: Fábián G, Gábris K, Tarján I Gyermekfogászat, Fogszabályozás és Állcsont-Ortopédia,  
Gallatz K: Fogak fejlődése – Tantermi előadás

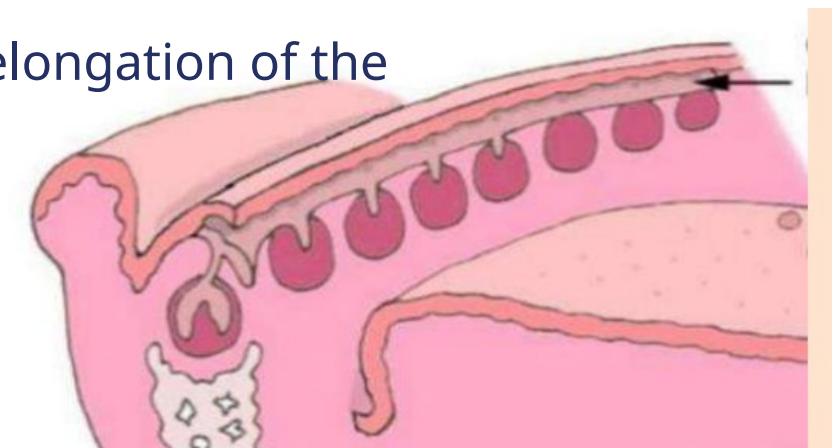

# Tooth development

## Primary tooth:

- on the lamina dentalis of the lower and upper jaw, 10-10 primary teeth are formed
- by the 6th intrauterine month, all primary teeth develop

## Permanent tooth:

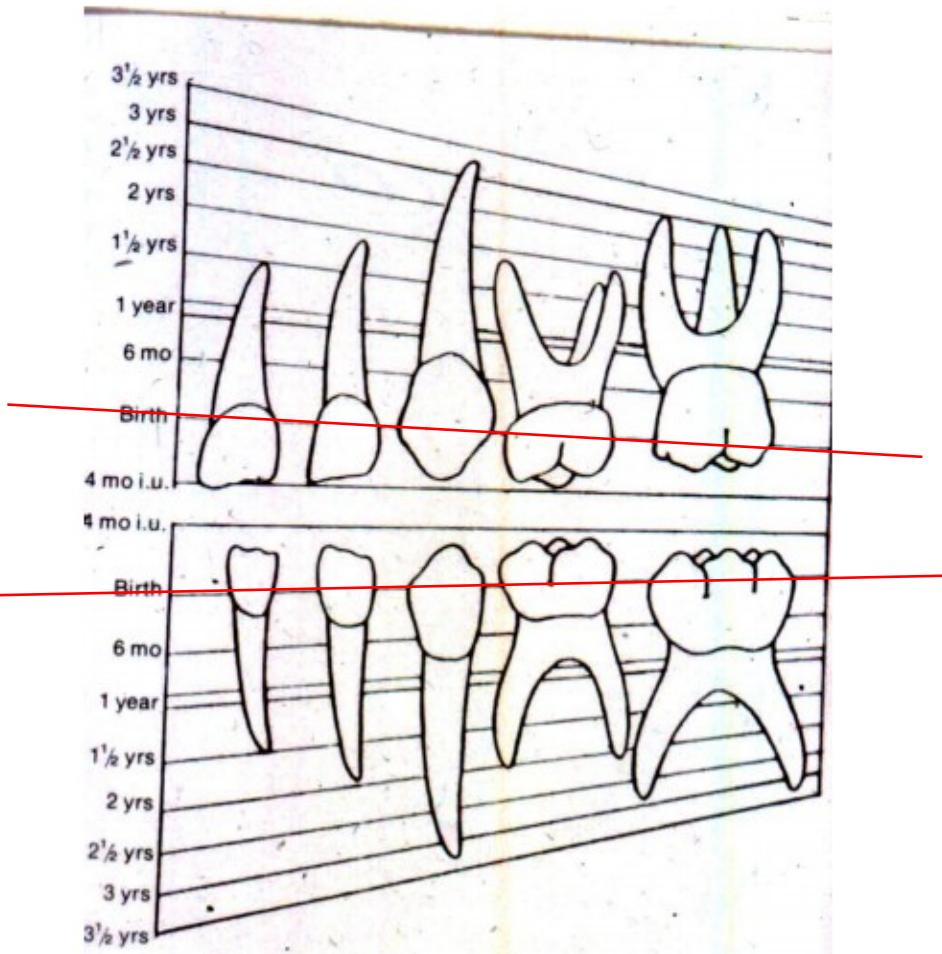

- Permanent tooth buds develop lingually/palatally compared to primary tooth buds
- They are mute until the age of 6
- Molars, on the other hand, develop in connection with the elongation of the lamina dentalis
- Gubernaculum Cordii is responsible for the correct position

Gallatz K: Fogak fejlődése – Tantermi előadás

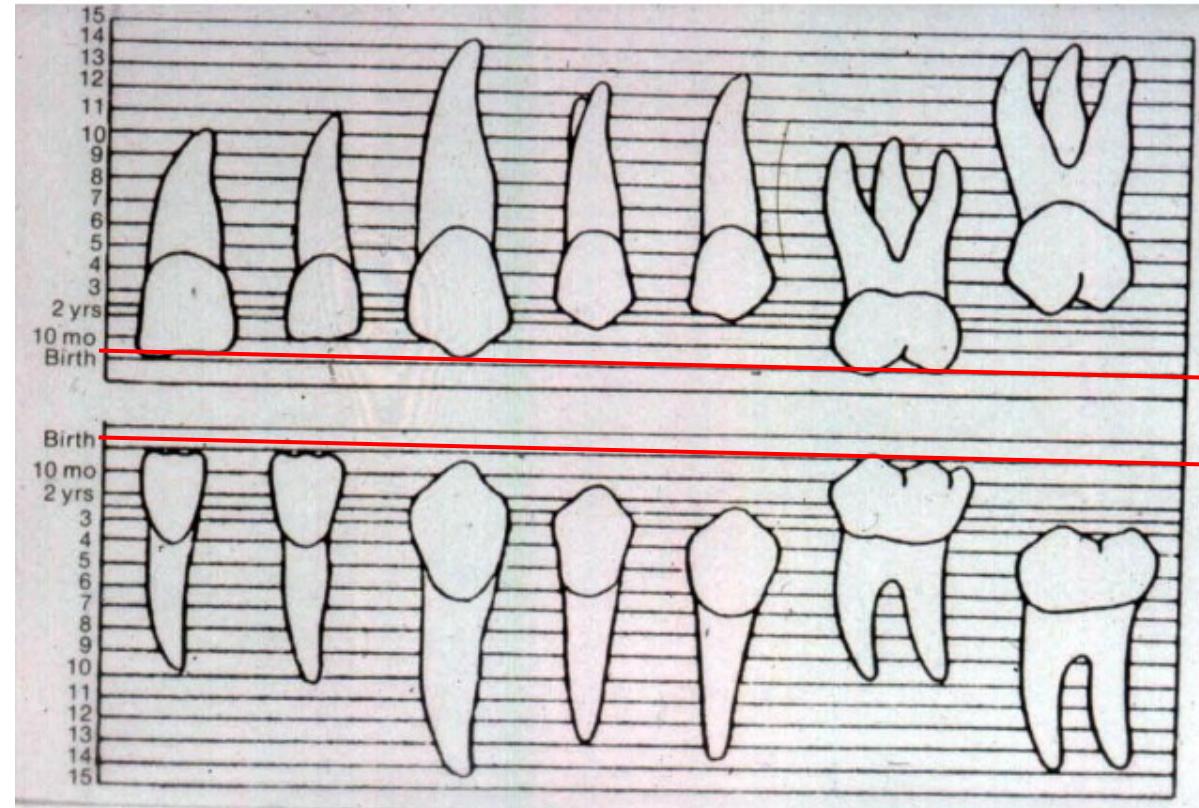

# Chronology of the mineralization of primary teeth

- It starts intrauterine and ends extrauterine
- Incisors: 17th embryonic week
- Molars: approx. 20th embryonic week
- Birth: The crowns of the incisors and canines are almost completely formed. The crowns of the molars are approx. semi-mineralized.

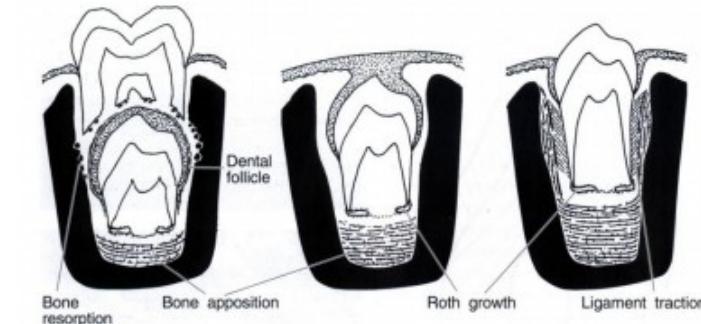

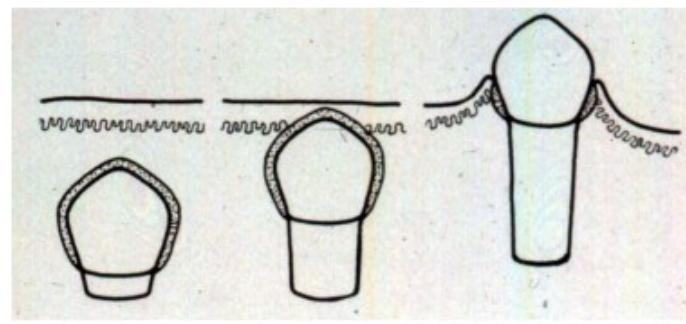

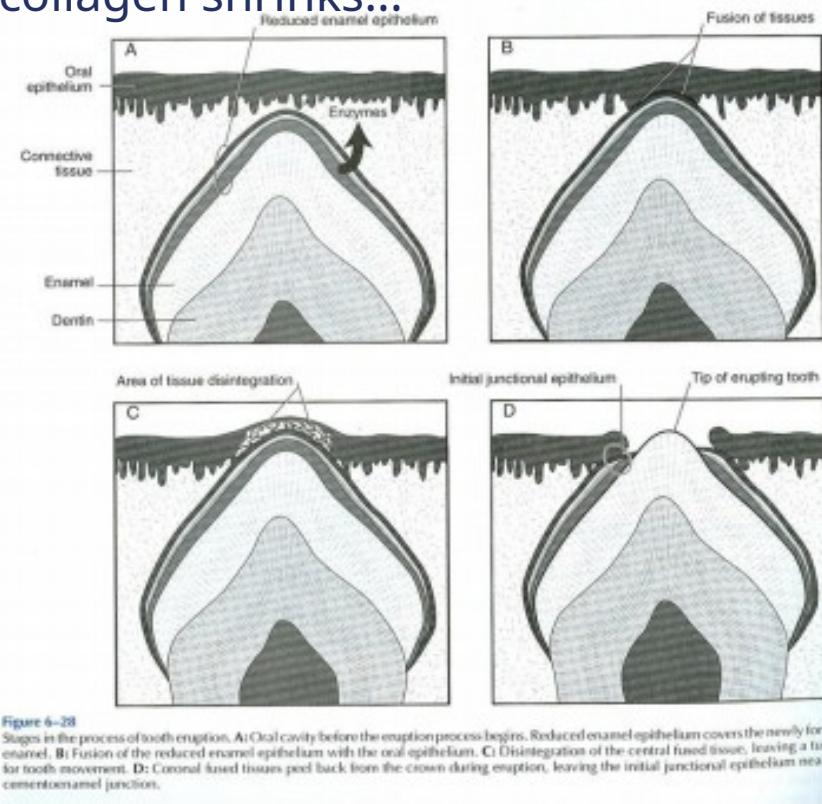

# Chronology of mineralization of permanent teeth

- Extrauterin

# Eruption of primary teeth

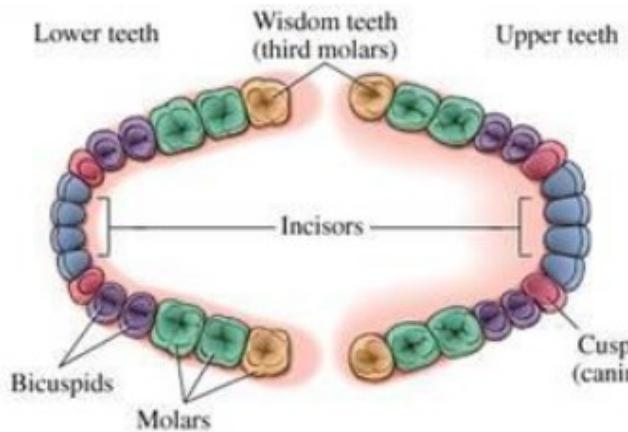

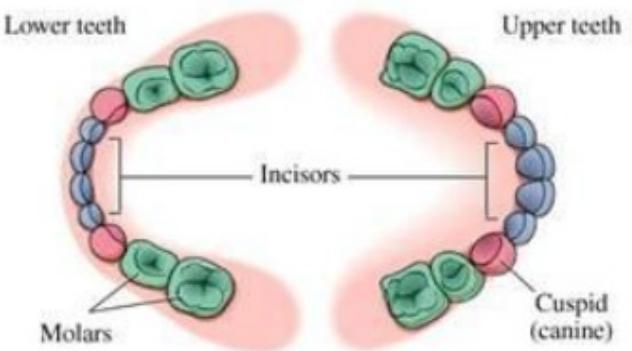

The thinned enamel epithelium merges with the oral epithelium, the hydrostatic pressure of surrounding tissues increases, collagen shrinks...

- 1. Preeruptive phase** (dental crown grows, osteoblasts)
- 2. Eruptive (prefunctional) phase** (tooth root grows, bone resorption, bone regeneration)
- 3. Posteruptive (functional) phase** (occlusion, tooth loss)

## Primary teeth

## Permanent teeth

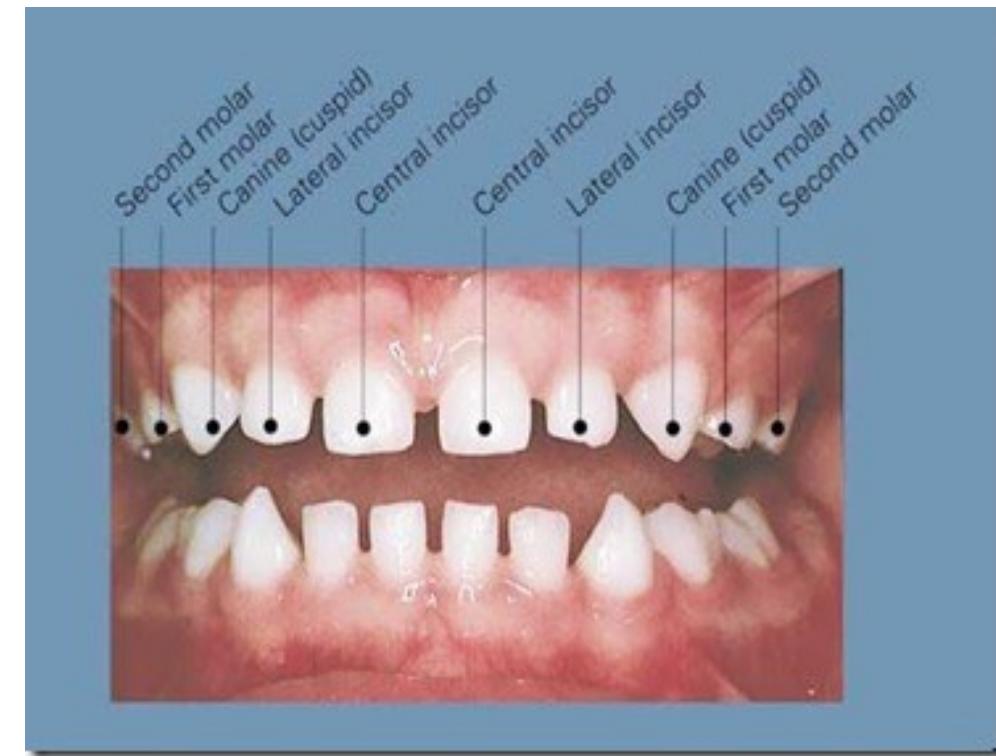

# Eruption of primary teeth

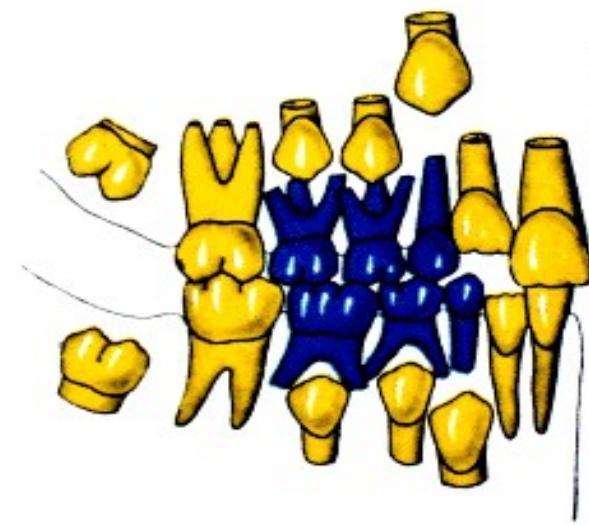

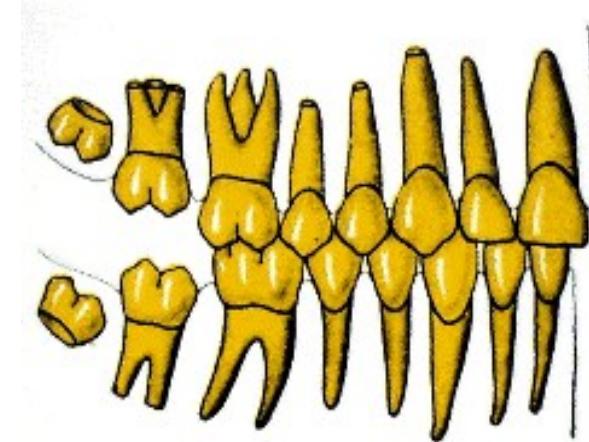

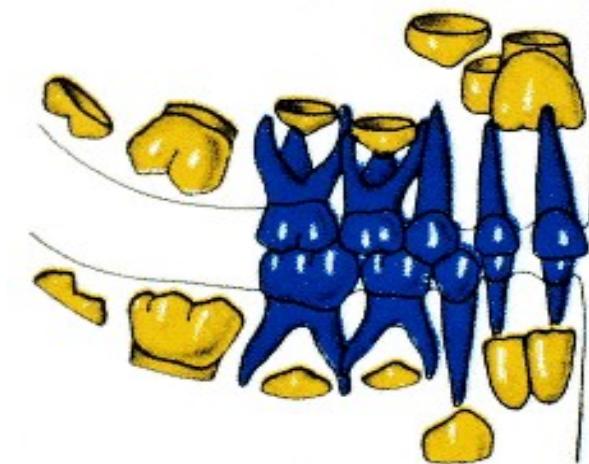

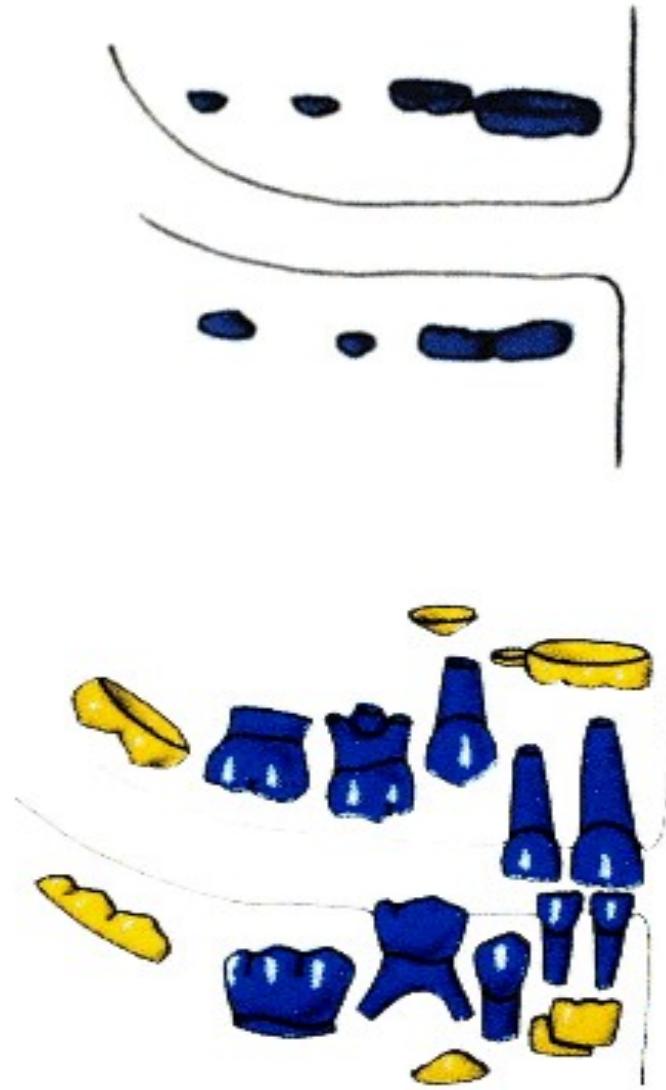

- Eruption of primary teeth ( 6 months-2.5-3 years): girls (usually) earlier, symmetrical, at the age of 2.5-3 years they all erupt
- medial incisor: 8-12 months (lower earlier than upper)
- lateral incisor: 9-13 months
- 1 molar: 13-19 months
- caninus: 16-22 months
- 2nd molar: 25-33 months

## Variations of abnormal eruption of deciduous teeth

- Dens connatalis
- Dens neonatalis
- Dentitio praecox
- Dentitio tarda
- Dentito difficilis

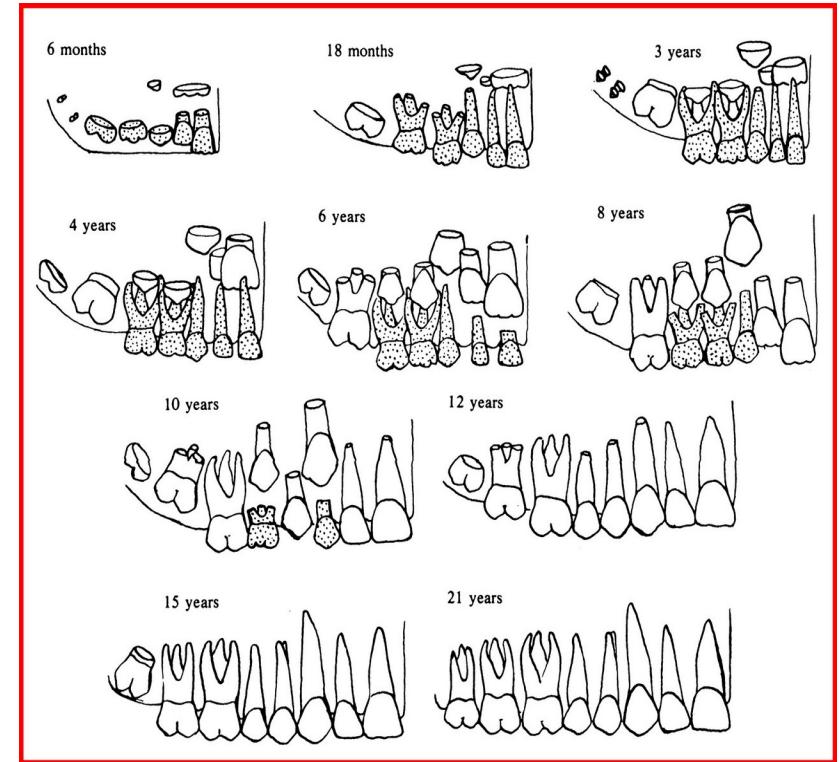

# Tooth eruption

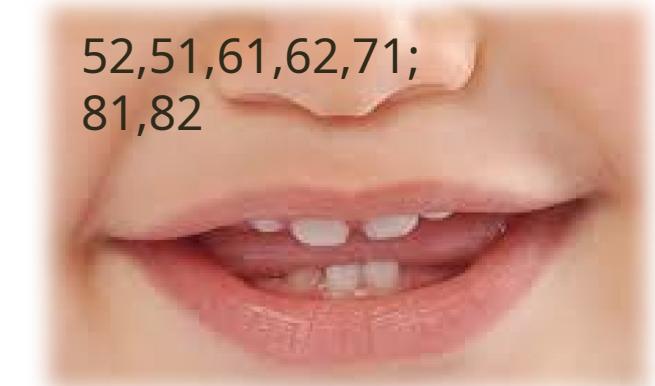

# Tooth eruption:

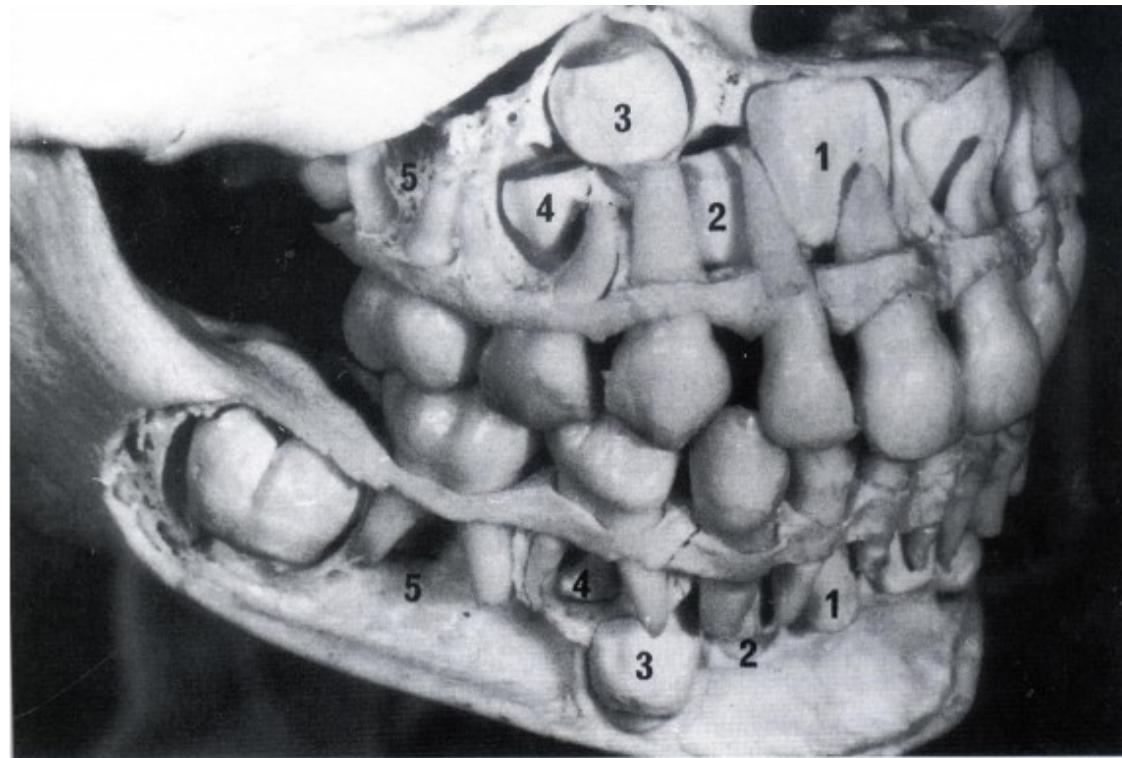

- ↳ 0-3 years - eruption of primary teeth
- ↳ 3-6 years of primary teething period
- ↳ 6-12 years mixed dentition
  - Early mixed 6-8 years
  - Late mixed 8-12 years
- ↳ 12-year permanent dentition

# Tooth eruption

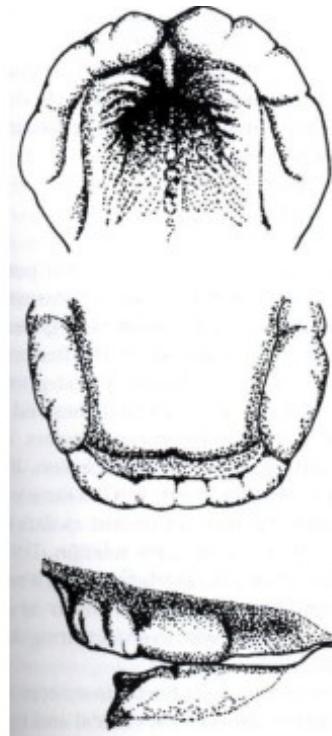

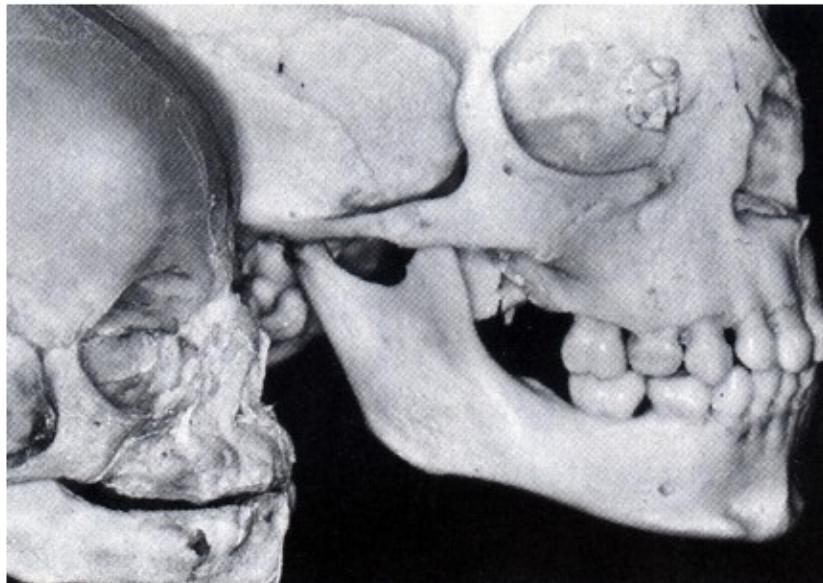

# Relations between the roots of primary teeth and the developing crowns of the permanent teeth during the functional stage of the primary dentition

# Jaw relations during primary tooth eruption

The eruption of primary teeth is accompanied by the development of the alveolar processes with considerable increase in facial height

At birth:

The gum pads are low, slightly lobulated and the palatal vault is flat; the mandible is retruded

Dr. Beck Anita  
Dr. Macsali Réka

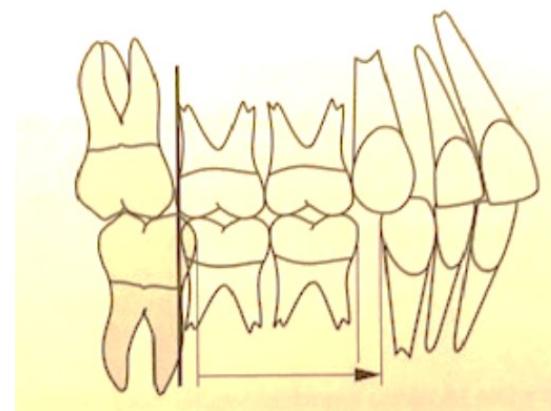

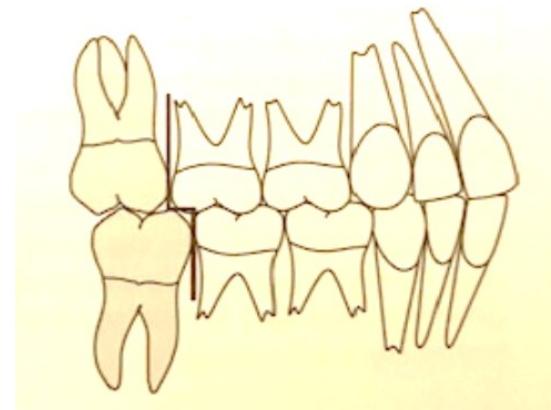

# Primary dentition-gaps

- Phisiological diastema (treme)

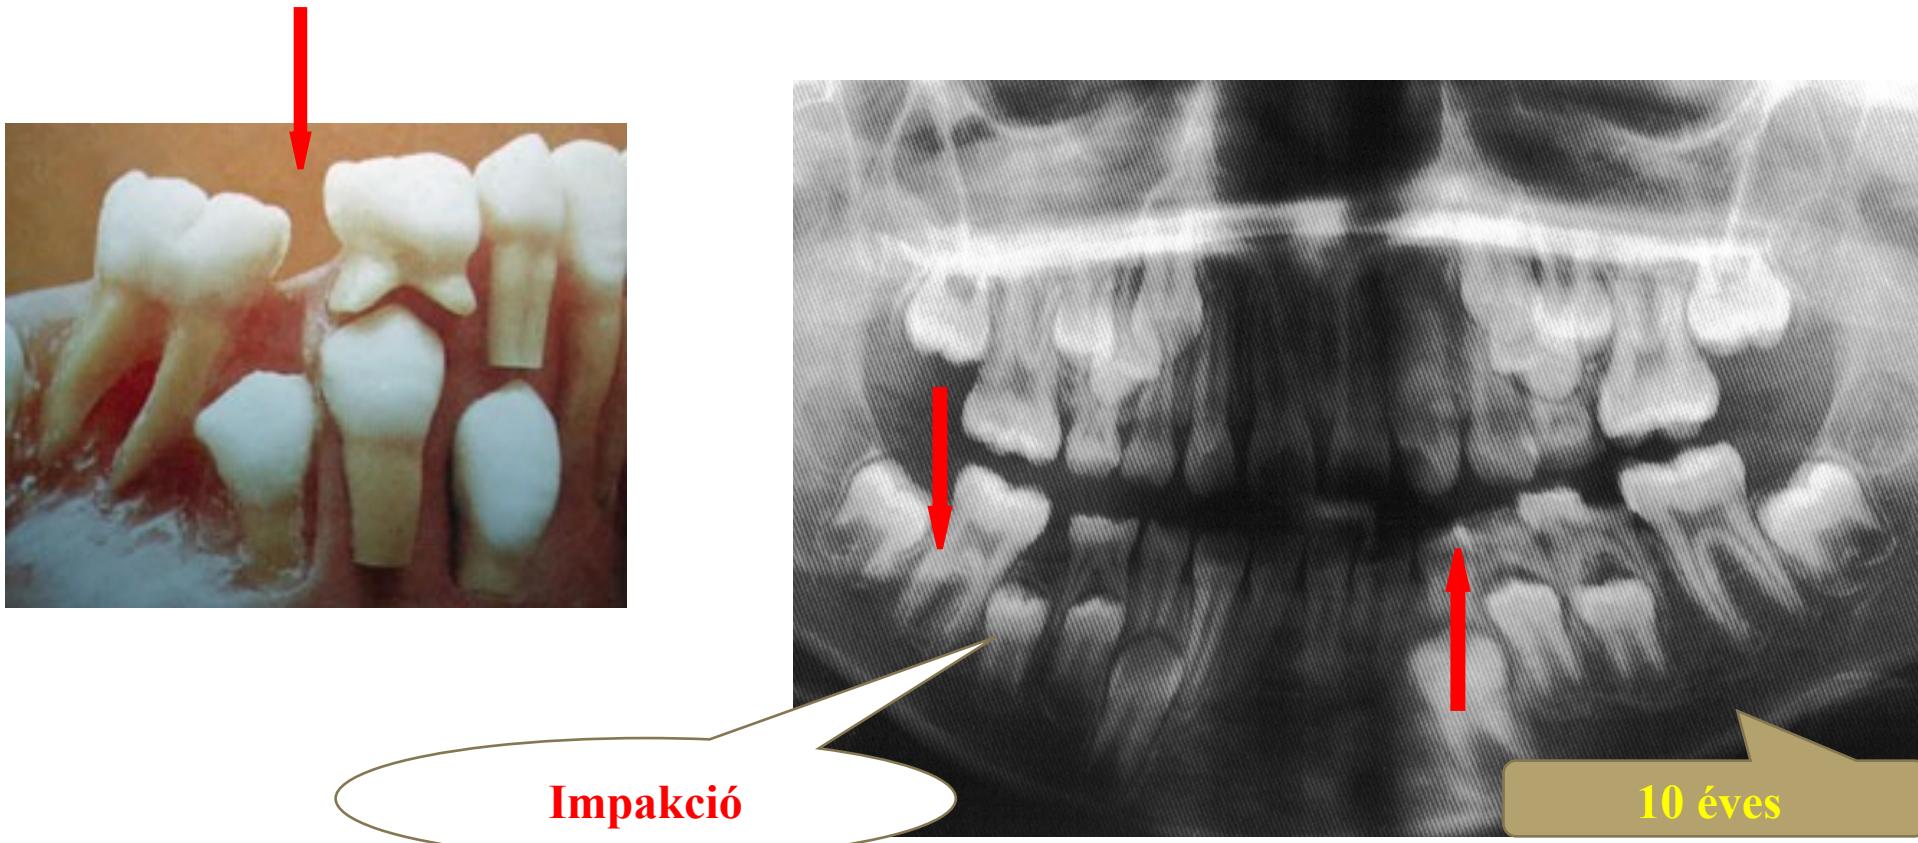

# Mesial step

When there is a mesial step in the terminal plane of the primary dentition, the permanent molars may erupt directly into normal occlusion

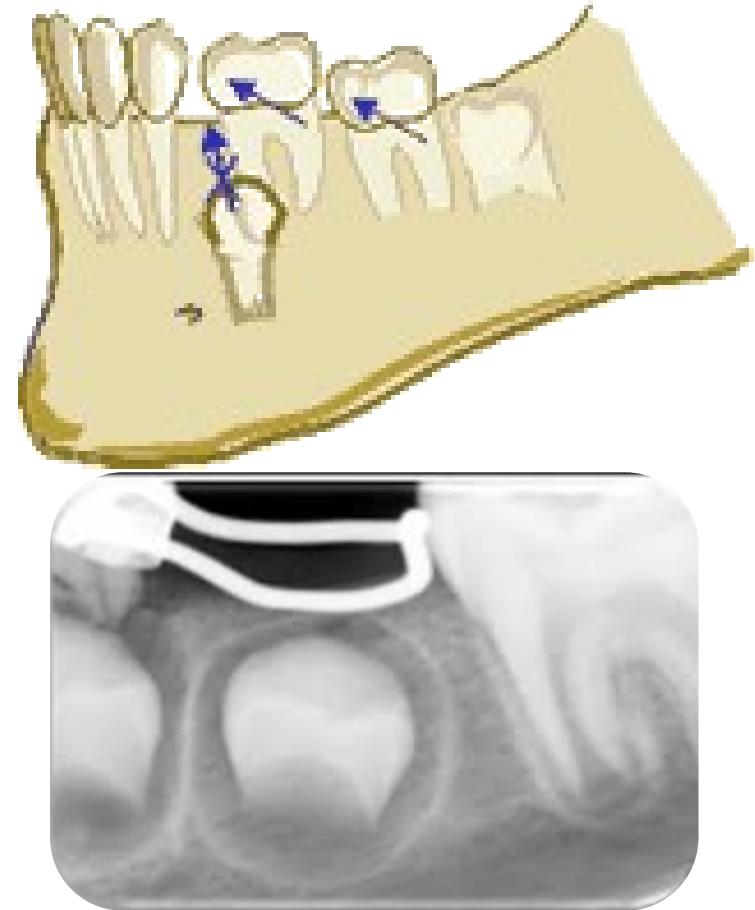

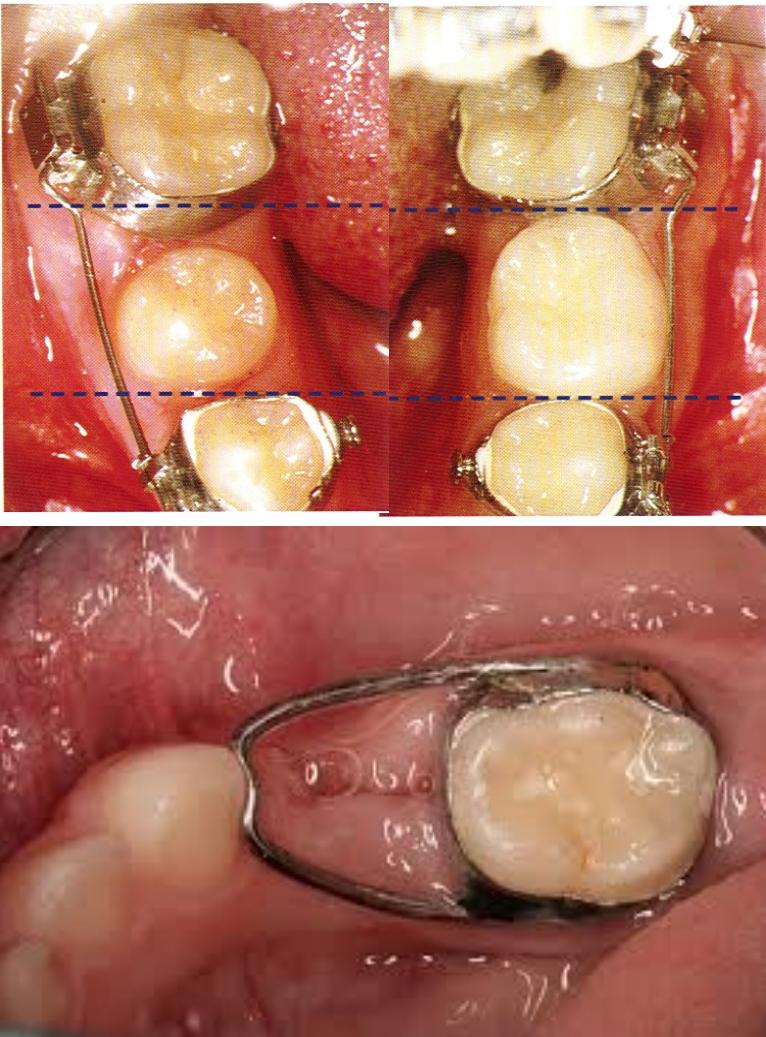

# Early extraction of primary tooth

# Space maintainer

E-space

Dr. Beck Anita  
Dr. Macsali Réka

# The position of the germs of permanent incisors

- The permanent upper incisors are more labially inclined than their primary predecessors. Consequently, the dental arch becomes wider and longer

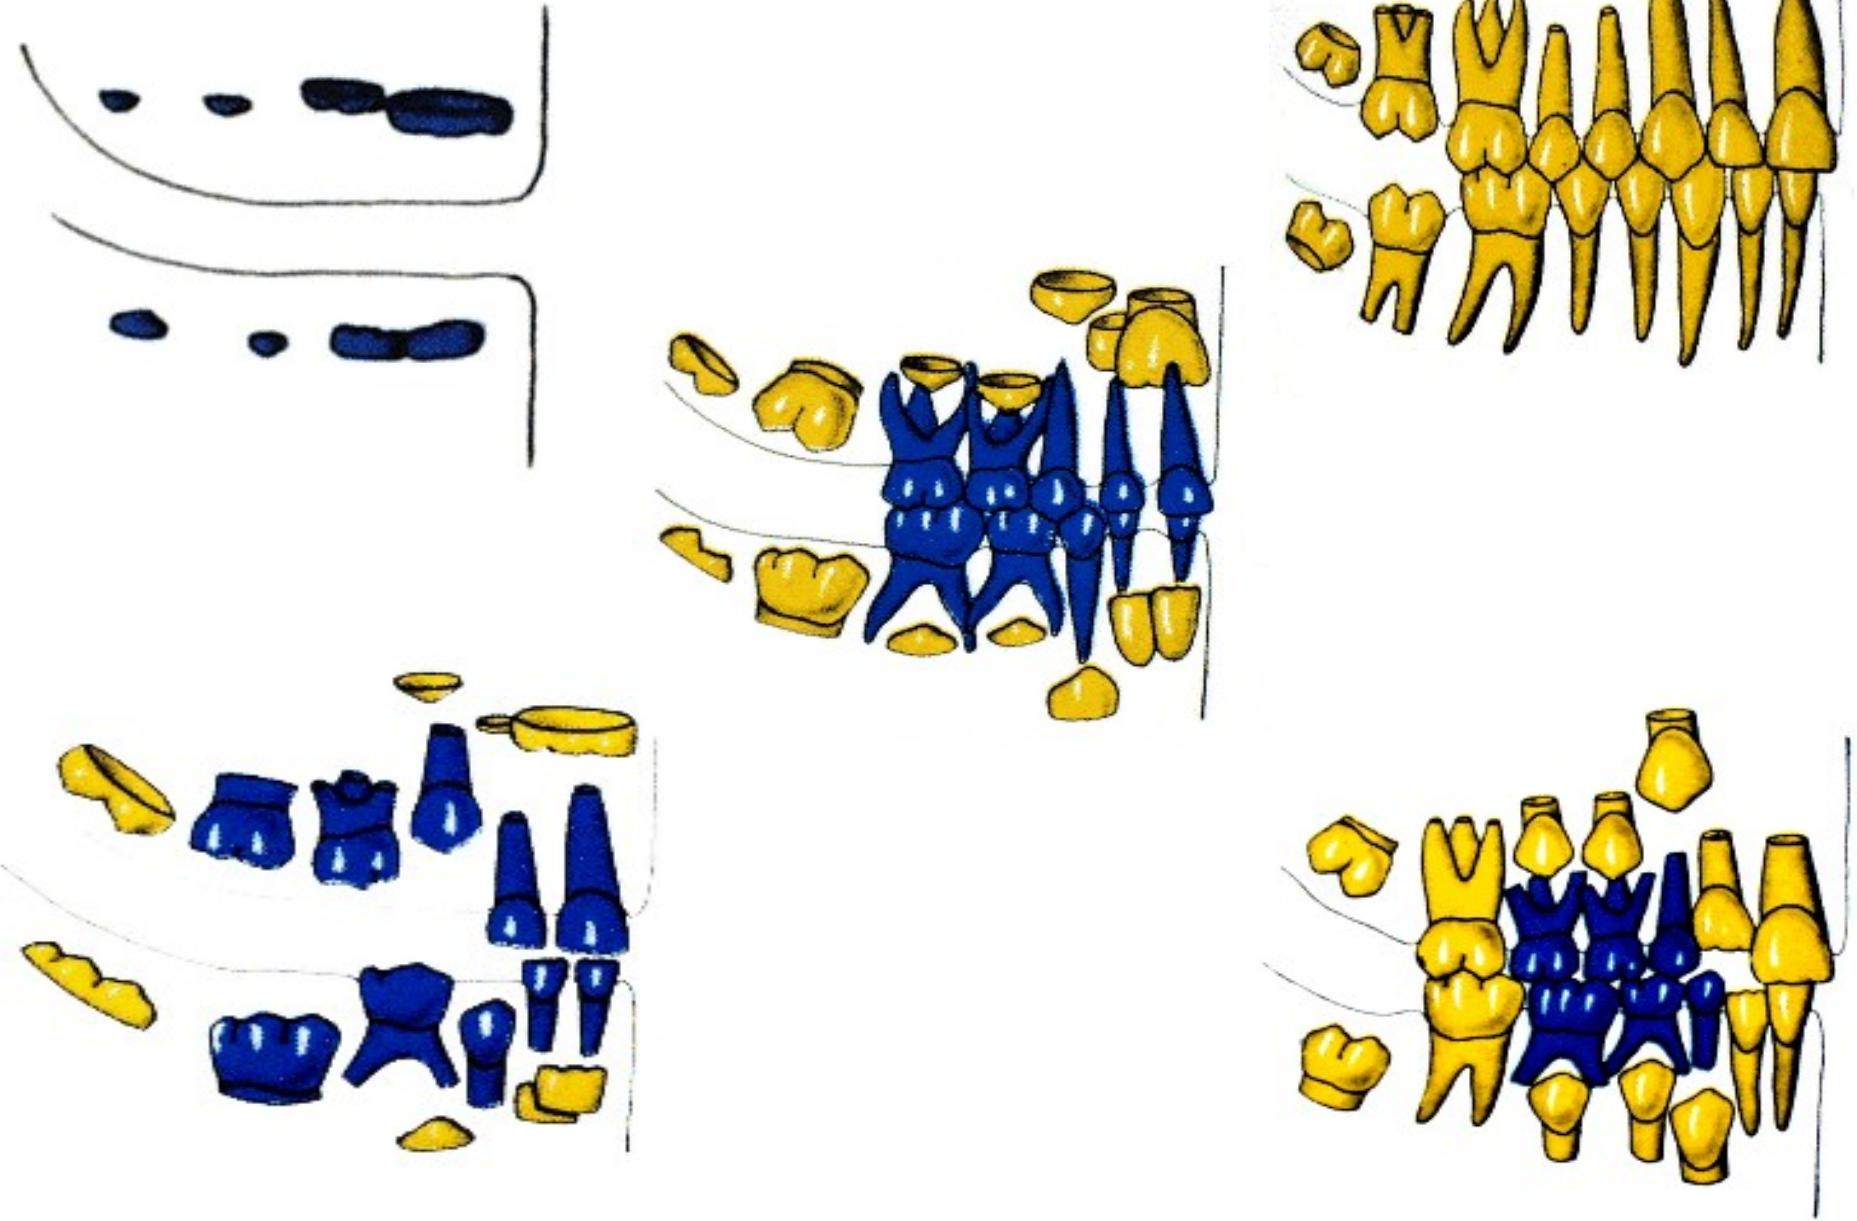

Képek forrása: Ch. Siplieth: *Kinderzahnheilkunde in der Praxis*,  
Quintessence Verlag, 2002.

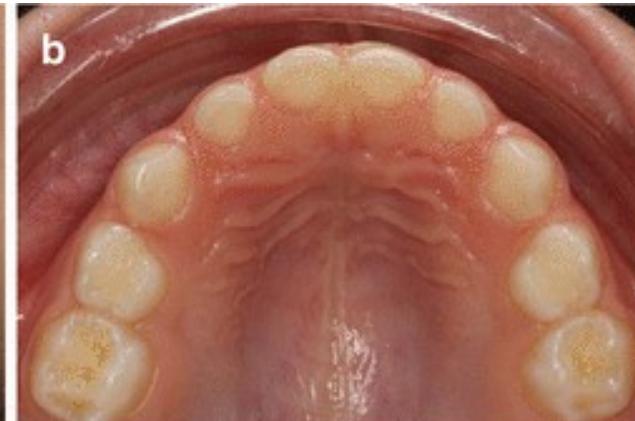

- Diastema medianum
- Eruption of upper canines
- Root pressure of lateral incisors

# In case of primary dentition the focus should be on:

- Prevention
- Primary tooth filling
- Consequences of tooth decay
- Space mainteteners
- Prevention of bad habits

During dentition, the wider deciduous molars are replaced by narrower premolars in the mesio-distal direction.

Physiological root resorption in deciduous teeth is a genetically determined feature of human dentition. Its smooth flow is one of the conditions for problem-free tooth changing.

Dr. Macsali Réka

# Symptoms of tooth eruption

- Feeling of pressure and pain
- Itch
- Increased salivation
- diarrhea / foul-smelling stools/ obstipation
- Increase body temperature, very rarely fever (37 - 38°C),
- Restlessness, irritability, even aggressiveness?
- Sleep disturbance, insomnia

Cooled chews (but not from the freezer!)

Gentle massage of the dental ridge

Alternative remedy: massaging the reflex zones of the toes

# Medicines:

**Dentinox®-Gel N:** Active ingredients: Chamomile tincture, lidocaine hydrochloride, macrogollauryl ether

Carrier material: xylitol, Free from dyes and preservatives

Effect: Pain relief, anti-inflammatory, promotion of wound healing,

**Dologel:** contains Veleriana, chamomile and propolis

**Gengigel-** From the first teeth: Contains Sodium Hyaluronate

**Anaftyn Baby:** Water, PVP, propylene glycol, PEG-40 hydrogenated castor oil, Aloe barbadensis, xanthan gum, aroma, potassium sorbate, sodium benzoate, disodium EDTA, sodium hyaluronate, xylitol, cetylpyridinium chloride, glycrrhetic acid, Crocus sativus.

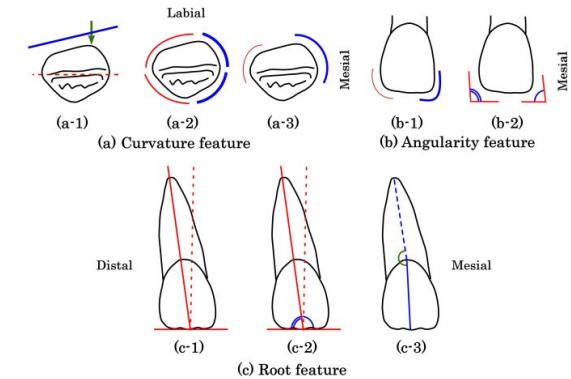

**Bedegel:** chamomile flower, valerian root, propolis, medicinal sage

# Anatomy of primary teeth

- 💡 they are usually smaller than the permanent
- 💡 rare individual variation
- 💡 colour: blue-white
- 💡 enamel mineralisation
- 💡 cervically: cingulum
- 💡 thinner layer of enamel and dentin
- 💡 roots are small, fracturing often
- 💡 Wide pulp chamber
- 💡 physiological root resorption: genetical

Mühlreiter's signs:

. Shintaro Kondo et al. The biological significance of tooth identification based on developmental and evolutionary viewpoints Journal of Oral Biosciences 2022. 64,3;287-302

# FDI: 51, 61

- wide, mesiodistal curvature more pronounced than incisocervical
- there is no tuberculum dentis
- expressed cingulum
- expressed palatal marginal edge
- deep fovea dentis
- cutting edge is smooth, straight (initially jagged, then wears off)

Begining of calcification	3-4 month intrauterin
Crown developing	4 month
Eruption to occlusion	7,5 month
Root developement	1,5 years

# FDI:52,62

- similar to the upper medial incisor, but! Smaller
- incisocervically longer than mesiodistally

Begining of calcification	4,5 month intrauterin
Crown developing	5 month
Eruption to occlusion	8-9 month
Root developement	1,5-2 years

# FDI: 71, 81

- lingually smooth
- expressed cingulum
- the marginal edge (limbus dentis) is not pronounced
- shallow fossa linguialis
- CEJ: mesially larger than distally
- chewing edge: divides the lingual and labial parts equally
- root: long, straight, round cross-section

Begining of calcification	4,5 month intrauterin
Crown developing	4 month
Eruption to occlusion	6,5 month
Root developement	1,5-2 years

# FDI: 72, 82

- crown wider, longer
- expressed cingulum
- deep lingual fossa
- chewing edge slopes distally
- distoincisal angle rounded
- crown is not symmetrical
- the cingulum is towards the distal
- root: lower 1/3 slopes towards the distal, can be a longitudinal furrow distally

Begining of calcification	4,5 month intrauterin
Crown developing	4,5 month
Eruption to occlusion	7 month
Root development	1,5-2 years

**FDI:53,63**

- longer crown
- expressed peaks
- mesial and distal edges are rounder
- the mesial slope of the apex is longer than the distal one
- expressed cingulum, limbus dental, palatal crest
- root length is twice the length of the crown

Begining of calcification	5 month intrauterin
Crown developing	9 month
Eruption to occlusion	16-20 month
Root developement	2,5-3 years

# FDI:54,64

MB. enamel thickening: tuberculum molare  
- occlusally brick or buccopalatally compressed elliptical  
-4 nipples: MB, MP, DB, DP  
-occlusally H-shaped depression: central fossa + mesial+distal  
- buccal groove  
-root: similar to permanent molar, but shorter root trunk, thinner roots  
-The palatal root is the longest, there are also MB and DB

Begining of calcification	5 month intrauterin
Crown developing	6 month
Eruption to occlusio	16-20 month
Root developement	2-2,5 years

# FDI:55,65

the crown is bigger than the top first one

- similar first permanent, only smaller
- has Tuberculum Carabelli

Begining of calcification	6 month intrauterin
Crown developing	10-12 month
Eruption to occlusio	1,75-2 év
Root developement	3 years

**FDI:84,74**

- cervically located buccal edge
- crown mesio-lingually rounder
- irregular chewing surface: brick or ellipse compressed in the buccolingual direction
- there is an enamel bump
- 4 cusps
- 2 roots

Begining of calcification	5 month intrauterin
Crown developing	6 month
Eruption to occlusio	12-16 hó
Root developement	2-2,5years
